

Software Requirements Specification (SRS)

1. Project Title

EasyApply – AI-Powered Job Application Management System

2. Project Description

EasyApply is a web-based application designed to help students and job seekers manage and optimize their job and internship applications efficiently.

The system centralizes job tracking, resume management, interview preparation, and AI-powered career assistance into a single platform. It replaces messy spreadsheets and scattered notes with a structured, data-driven dashboard.

The platform also integrates AI features that analyze resumes, suggest improvements, generate interview questions, and provide job-fit insights.

Features

1. User Profile Management

Users can create and manage their professional profile including education, skills, experience, preferred roles, and job locations. This data will be used by the AI API to generate personalized suggestions. Profile information can be updated anytime.

2. Job Application Creation

Users can add, edit, delete, and view job applications. Each entry stores company name, role, job link, salary (optional), and notes. This forms the core tracking system of the platform.

3. Application Status Pipeline

Each job moves through customizable stages such as Saved, Applied, Interview, Offer, or Rejected. Status changes are stored in the database. This helps users visually manage their job pipeline.

4. Saved Jobs / Wishlist

Users can save job opportunities before applying. Saved jobs can later be converted into full applications. This helps organize future opportunities separately.

5. Resume Upload & Version Management

Users can upload multiple resume versions (PDF/DOC). Each resume can be linked to a specific job application. Files are stored securely on the server or cloud storage.

6. Centralized Dashboard

Shows:

- Total applications
- Active applications
- Interviews scheduled
- Offer rate
- Rejection rate

7. AI Resume Review

The system sends the resume text and job description to an AI API. The API returns feedback about improvements, clarity, and keyword optimization. The response is displayed in a structured feedback panel.

8. AI Resume–Job Matching Feedback

Using the AI API, the system compares resume content with job description. Instead of calculating complex scores, the AI returns a textual evaluation explaining fit level and missing skills. This keeps implementation simple but powerful.

9. AI Bullet Point Improvement

Users can paste a resume bullet point and send it to the AI API. The API rewrites it to be more professional, quantified, and impactful. The user can copy or replace it directly.

10. AI Cover Letter Generator

Based on job description and user profile, the system calls the AI API to generate a tailored cover letter draft. Users can regenerate or edit the response before downloading.

11. AI Interview Question Generator

The system sends job description and role title to the AI API. The API returns likely technical and HR questions. These questions are saved under the application for interview preparation.

12. Interview Notes Management

Users can store interview experiences, questions asked, and feedback received. This creates a personal interview knowledge base. Notes remain linked to each job entry.

13. Interview Schedule & Reminder

Users can store interview date and time. The dashboard displays upcoming interviews and highlights urgent ones. Basic reminder logic is implemented using date comparison.

14. Application Deadline Reminder

Users can set application deadlines. The system automatically highlights deadlines that are near or expired. This prevents missed opportunities.

15. Dashboard & Basic Analytics

The dashboard shows total applications, interviews, offers, and rejection counts. Simple charts (using a React chart library) visualize statistics. All calculations are basic database counts.

16. Application Search & Filter

Users can search applications by company name, role, or status. Filters allow viewing only interviews, only rejected jobs, etc. This improves usability for large datasets.

17. Activity Log per Application

Each application shows a simple timeline of actions (created, status changed, interview added). This is implemented using timestamps stored in MongoDB. No complex audit system required.

18. Export Application Data

Users can export their job applications as CSV. This allows backup and offline analysis. Implementation uses simple backend CSV generation.

19. Notes & Document Attachment

Users can attach additional files (portfolio, transcripts, certificates) to applications. Notes section allows storing recruiter contact details or special instructions.

20. Secure API-Based AI Integration Layer

All AI features are handled via structured API requests to an external AI service. The backend manages API keys securely. Error handling and response formatting ensure smooth user experience.
